

# The Impact of Student Grade-Level on the Honors Algebra I Midterm Exam Results 

Technical Report

Clint Sattler<br>Supervisor, Research and Evaluation<br>Knox County Schools Department of Research, Evaluation, and Assessment

January 2018

## Overview

The number of $7^{\text {th }}$ grade students enrolled in Honors Algebra I increased dramatically during the 2017-2018 school year (SY1718) in the Knox County Schools (KCS). Twenty-five 7th grade students were enrolled in Honors Algebra I in SY1617 and sixty-three $7^{\text {th }}$ grade students were enrolled in SY1718.

The available literature offers diverging views regarding the benefits of accelerating students in their mathematical instruction. Some studies have documented positive effects when exposing students to rigorous Algebra instruction regardless of prior math performance and student demographics (Gamoran, 2000, Domina, 2014). Similar findings have spurred states and districts to champion "Algebra for all" initiatives, but the results of these initiatives have been somewhat mixed (Nomi, 2012). Some research also suggests that acceleration of math instruction is correlated to negative effects in the near-term (Clofelter, 2015, Marsh, 2016). These negative effects are possibly related to "gaps" in student knowledge (due to missing instruction in grade-level curriculum) and these "gaps" can compound as students progress to more advanced mathematical content (Loveless, 2008).

The KCS Mathematics Supervisor asked the Department of Research, Evaluation and Assessment to analyze the impact student grade-level may have on Algebra I outcomes. Results from the SY1718 (district created) Honors Algebra I midterm exam were chosen as the data source for this preliminary study. Using the midterm exam results allows KCS to understand the dynamics of student learning prior to the release of any state test results.

Methodology
Hierarchical Linear Modeling (HLM) was used to model student performance on the Honors Algebra I midterm exam because of the nested structure of the data. The student-level data was nested under two entities: teacher and school. A three-level HLM with random intercepts at both the school and teacher levels was used to model the data. The analysis included two independent variables at the student level. No group-level independent variables were included at the teacher and school levels.

One of the HLM independent variables was a measure of student academic ability. Projected state percentiles for the Algebra I End-of-Course (EOC) state exam were chosen as the most appropriate measures of student ability. These values were available via the Tennessee Value Added Assessment System (TVAAS) and were derived from past performance on state assessments. Projected state percentiles were converted to normal curve equivalents (NCEs) and squared. The inverse of the resulting squared NCEs were normalized in an effort to linearize the data to the maximum extent possible.

The other independent variable included in the HLM model was the students' grade-level. Student grade-levels were entered as factors into the HLM model with $8^{\text {th }}$ grade set as the reference level. The dependent variable in the HLM regression was the normalized percent of correct responses on the Honors Algebra I midterm exam.

Honors Algebra I midterm exam results were available for 1,096 KCS middle school students. Sixteen student records were removed from the sample due to missing Algebra I TVAAS projections, leaving 1,080 records for statistical modeling. HLM was completed in R version 3.4.3 and RStudio version 1.0.143 using the lme4 package.

## Results

The raw statistics from the Honors Algebra I midterm are contained in Table 1.

Table 1: Honors Algebra I Midterm Statistics

| Mean \% <br> Correct | Standard <br> Deviation | 1st <br> Quartile | Median | 3rd <br> Quartile | Minimum <br> Score | Maximum <br> Score |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $81.5 \%$ | $15.4 \%$ | $75.0 \%$ | $85.0 \%$ | $95.0 \%$ | $15.0 \%$ | $100 \%$ |

The HLM model used to fit the data was as follows:

$$
\begin{gathered}
y_{i j k}=\pi_{0 j k}+\pi_{1} * \text { Prev.Ach }+\pi_{2} * \text { Grade Level }+\epsilon_{i j k} \\
\pi_{0 j k}=\beta_{00 k}+r_{0 j k} \\
\beta_{00 k}=\gamma_{000}+\mu_{00 k}
\end{gathered}
$$

The prediction model appears to fit the observed data satisfactorily (Figure 1). Readers should note that there was a significant portion of variance in student performance on the Honors Algebra I midterm exam that was not described by the model.

Figure 1: Observed Vs. Predicted (HLM) Values
Residual analysis indicates that the fit to the model may contain some bias because of nonlinearies in the data. This is most likely due to low outliers and ceiling effects (no student could score higher than $100 \%$ ). The histogram and Q-Q plot of the residuals are contained in Figures 2 and 3 respectively. Efforts were made to transform the raw data (using inverse, square root, and logarithmic transformations) to obtain a better fit but without success. Winnowing of the sample was not attempted since there was no empirical or theoretical reason to remove outlier data.

Figure 2: Histogram of HLM Residuals

Figure 3: Q-Q Plot of HLM Residuals

The Impact of Student Grade-Level on the Honors Algebra I Midterm Exam Results

The parameter estimates and the statistics associated with the fixed effects are available in Table 2. Random effects from the HLM regression (and their associated standard errors) are available in the appendix.

Table 2: HLM Fixed Effects

| Parameter | Estimate | Std. Error | t |
| :--- | :---: | :---: | :---: |
| Intercept | -0.16 | 0.15 | -1.02 |
| Projected State NCE (1/ NCE $^{2}$, normalized) | -0.37 | 0.02 | -15.13 |
| Grade $=7$ | -0.23 | 0.11 | -2.21 |
| Grade $=6$ | -0.09 | 0.30 | -0.30 |

We can reject the null hypothesis that the results of the Honors Algebra I midterm were no different for $7^{\text {th }}$ grade students when compared to $8^{\text {th }}$ grade students when all other factors were held constant ( $p=0.027, \alpha=0.05$ ). The magnitude of the difference was estimated at - 0.23 standard deviations, which correlated to $3.6 \%$ of the points available on the test. In practical terms, an Honors Algebra I student who was in $7^{\text {th }}$ grade would be expected to miss approximately $3 / 4$ of a question more than an $8^{\text {th }}$ grade student with a similar academic history and the same teacher/school assignment. When the standard error of the estimate is considered, a $7^{\text {th }}$ grade student would be expected to miss anywhere between $1 / 4$ and $11 / 4$ more questions than an $8^{\text {th }}$ grade student with similar academic history and the same teacher/school assignment.

## Conclusions \& Considerations

After controlling for previous academic performance, teacher assignment and school assignment, there was evidence that $8^{\text {th }}$ grade students were likely to outperform $7^{\text {th }}$ grade students on the Honors Algebra I midterm exam. It is estimated that $7^{\text {th }}$ grade students missed between $1 / 4$ and $11 / 4$ questions more than $8^{\text {th }}$ grade students with similar academic history and the same teacher/school assignment. Although this finding is statistically significant, it may not be practically significant due to the relatively small magnitude of the difference.

Future studies should determine if similar results are detectable on external summative exams. The Knox County Schools should try to understand the impact of missing direct instruction of the $7^{\text {th }}$ and $8^{\text {th }}$ grade math curriculum on results in state or national exams relating to Algebra I, Geometry, and more advanced math topics.
